

Given  $D = \{x_i, y_i\}_{i=1}^n$

Here  $x_i$  belongs to  $\mathbb{R}^d$  (here  $d$  is dimensions, for iris it's 4), for example here  $x_i$  is the column vector, for iris dataset  $x_1$  will be  $[1, 4, 6, 4]$  each is SL, SW, PL, PW.

And  $y_i$  belongs to any of the class label that is for iris it may be **setosa, versicolor, virginica**.

In a dataset  $D = \{x, y\}$ , ' $x$ ' represents the input vector and ' $y$ ' represents the output label/value.

### Comments:

- For a single value,  $X$  will be a column vector and  $y$  will be a single value. But for an entire dataset  $X$  will be a matrix and  $Y$  will be a column vector.

Example:

that means for a datapoint  $y_i$  belong to real number and is a scalar value not a vector ; for example :

$(x_i, y_i)$  where  $x_i = (\text{height}, \text{weight}, \text{age})$  ;  $y_i = \text{gender}\{0:\text{Male}; 1:\text{Female}\}$  , so lets say  $x_i(179\text{cm}, 75\text{kg}, 24)$  ;  $y_i(0)$

. But if we consider all the  $n$  points then  $Y$  is a column vector of size  $n$

- As we represent all the data points as  $\mathbb{R}^d$  and writing it as  $x_i \in \mathbb{R}^d$ , what will be the representation for all the class label ?  $y$ ?

In case of regression problem :  $y \in \mathbb{R}$

In case of binary classification problem:  $y \in \{0, 1\}$
